Introduction

Welcome to the [Attacking Web Applications with Ffuf](#) module!

There are many tools and methods to utilize for directory and parameter fuzzing/brute-forcing. In this module we will mainly focus on the [ffuf](#) tool for web fuzzing, as it is one of the most common and reliable tools available for web fuzzing.

The following topics will be discussed:

- Fuzzing for directories
- Fuzzing for files and extensions
- Identifying hidden vhosts
- Fuzzing for PHP parameters
- Fuzzing for parameter values

Tools such as [ffuf](#) provide us with a handy automated way to fuzz the web application's individual components or a web page. This means, for example, that we use a list that is used to send requests to the webserver if the page with the name from our list exists on the webserver. If we get a response code 200, then we know that this page exists on the webserver, and we can look at it manually.
